NEW METHOD OF DETERMINING THE CURRENT CARRIER CONCENTRATION IN A SUBSTANCE IN THE STATE OF SUPERCONDUCTIVITY

F. P. Golotyuk

This report proposes a fundamentally new solution to the problem of determining the current carrier concentration in a substance. The basis of the corresponding experimental method is a theory which considers the electron drift energy when considering the oscillatory processes in certain circuits [1].

We will consider a circuit in which external voltage which varies according to the law $U = U_m \cos \omega t$ acts.

When considering the drift energy of the current carriers [1], the differential equation which describes the oscillatory process in a circuit with elements R , L , C has the form:

$$\frac{d^2 q}{dt^2} + 2\delta \frac{dq}{dt} + \omega_0^2 q = U_m \cos \omega t. \quad (1)$$

Here q is the charge on the capacitor plates, U_m is the amplitude of the applied voltage,

$$\delta = \frac{R}{2L(1+\lambda)}, \quad \omega_0 = \frac{1}{L(1+\lambda)C}. \quad (2)$$

λ in formula (2) is equal to the ratio of the carrier drift energy

to the magnetic field energy of the latter, and it is determined by the expression [1]

$$\lambda = \frac{ml}{Ln_0q_0^2S} = \frac{mR}{Ln_0q_0^2\rho}, \quad (3)$$

where m , q_0 and n_0 are the mass, charge and concentration of current carriers in the conductor from which the inductance is made; l , S and ρ are the length, cross section and specific electric resistance of the conductor. The solution of equation (1) makes it possible to obtain the relationship

$$U_{em} = \frac{U_m}{\omega C \sqrt{R^2 + [\omega L(1+\lambda) - \frac{1}{\omega C}]^2}}, \quad (4)$$

in which $U_{em} = \frac{q_m}{C}$ is the amplitude value of the voltage on the capacitor; q_m is the maximum charge on its plates.

If we make the inductance of the circuit from the conductor considered above in the form of a solenoid with a double-wound winding, the self inductance coefficient $L \approx 0$. Then, introducing the designation

$$T = \lambda L = \frac{ml}{n_0q_0^2S} = \frac{mR}{n_0q_0^2\rho} \quad (5)$$

and changing to the effective voltage values

$$U_{em}^{(eff)} = \frac{U_{em}}{\sqrt{2}}, \quad U_m^{(eff)} = \frac{U_m}{\sqrt{2}},$$

we will rewrite relationship (4) in the form

$$U_{em}^{(eff)} = \frac{U_m^{(eff)}}{\omega C \sqrt{R^2 + \left(\omega T - \frac{1}{\omega C}\right)^2}}. \quad (6)$$

Knowing the frequency ω , the voltage acting in the circuit, the capacitance, and the ohmic resistance of the circuit, and using a vacuum tube voltmeter to determine the voltages $U_{em}^{(eff)}$ and $U_m^{(eff)}$,

from formula (6) we can determine the value of τ , after which we find the current carrier concentration from expression (5). Obviously, the value of τ found from formula (6) will considerably exceed the error of measurement when the following conditions are satisfied

$$\omega\tau \gg \frac{1}{\omega_c \ell}, \quad (7)$$

$$\omega\tau - \frac{1}{\omega_c} \gg R. \quad (8)$$

As an example, we will consider the possibility of realizing conditions (7) and (8). Assuming that the solenoid is made from copper wire of length $\ell = 1000$ m, with a cross section $S = 10^{-8}$ m² and $n_0 = 10^{29}$ m⁻³ (there is one free electron per atom in the calculation), from formula (5) we obtain $\tau = 5 \cdot 10^{-11}$ H. With a voltage frequency of $f = \frac{\omega}{2\pi} = 100$ MHz and a capacitor capacitance of 10^{-4} F, $\frac{1}{\omega_c} = \frac{1}{100} \omega\tau$, so that condition (7) can actually be satisfied. Considering that $\frac{1}{\omega_c} \ll \tau\omega$, and also relationship (5), we will rewrite condition (8) in the form

$$\omega \gg \frac{R}{\tau} - \frac{n_0 q_0^2 \rho}{m}. \quad (9)$$

In our case, the numerical calculation gives us $\omega \approx 4 \cdot 10^{19}$ Hz; therefore, condition (9) cannot be realized. Since all metals have similar values of n_0 and ρ , if the solenoid is made from other metal conductors, the value of ω will be around 10^{19} Hz and it also is impossible to satisfy condition (9). But when the conductor is in the state of superconductivity ($R = 0$), condition (9) is satisfied.

Thus, the method in question of determining the current carrier concentration in a substance is appropriate when this substance is in the superconducting state.
